## CAT 2021 QA Solution Slot 1

Q1. Suppose the length of each side of a regular hexagon ABCDEF is 2 cm . If $T$ is the mid point of $C D$, then the length of $A T$, in cm , is 1. $\sqrt{ } 12$
2. 115
3. 114
4. $\sqrt{13}$

## Solution.

Given a regular hexagon $A B C D E F$ :

1. Draw a perpendicular from $A$ to side $C D$. Let this meet $C D$ at point $M$.
2. As $A B C D E F$ is a regular hexagon, each interior angle is $120^{\circ}$. So, the angle MAD is $30^{\circ}$.
3. $A D$ is the diagonal of the hexagon. Since $T$ is the midpoint of $C D, C T$ $=1 \mathrm{~cm}$ (half the length of side CD).
4. Triangle MAT is a 30-60-90 right triangle.

From the properties of a 30-60-90 right triangle:
$\backslash[\mathrm{MA}=\backslash$ frac $\{$ lsqrt $\{3\}\}\{2\}$ \times $A D \backslash]$
$\backslash[A T=\backslash f r a c\{1\}\{2\} \backslash$ times $A D \backslash]$
Given CM (or CT) is 1 cm ,
$\backslash[\mathrm{MA}=2$ times $\backslash \mathrm{sqrt}\{3\} \backslash \operatorname{text}\{\mathrm{cm}\} \backslash]$ (because $\backslash(\mathrm{MA}=\backslash \mathrm{sqrt}\{3\} \backslash$ times $C M$ ())

To find AD, we can use the Pythagoras theorem on triangle AMD:
$\backslash\left[A D^{\wedge} 2=A M^{\wedge} 2+M D^{\wedge} 2 \\right]$
$\backslash\left[D^{\wedge} 2=(2 \backslash \mathrm{sqrt}\{3\})^{\wedge} 2+2^{\wedge} 2 \backslash\right]$
$\\left[A D^{\wedge} 2=12+4=16 \\right]$

\[ $A D=4$ lext $\{\mathrm{cm}\} \backslash]$

Therefore,
$\backslash[$ AT $=\backslash$ frac $\{1\}\{2\} \backslash$ times $4=2 \backslash$ text $\{\mathrm{cm}\} \backslash]$
But, since $T$ is the midpoint, we also have $\backslash(T D=1 \backslash t e x t\{c m\} \backslash)$
Finally, using the Pythagoras theorem on triangle ATD:
[ $\left.A T^{\wedge} 2=A D^{\wedge} 2-D^{\wedge} 2 \\right]$
$\backslash\left[A T^{\wedge} 2=4^{\wedge} 2-1^{\wedge} 2=16-1=15 \\right]$
$\backslash[A T=\backslash$ sqrt $\{15\} \backslash]$
So, the correct answer is:
2. $\sqrt{ } 15$

## Q. 2 If,r is a constant such that $\left|x^{2}-4 x-13\right|=r$

 has exactly three distinct real roots. then the value of $r$ is1. 17
2. 15
3. 21
4. 18

## Solution.

Given the equation $\backslash\left(\left|x^{\wedge} 2-4 x-13\right|=r \backslash\right)$
The equation $\backslash\left(x^{\wedge} 2-4 x-13=r \backslash\right)$ or $\backslash\left(x^{\wedge} 2-4 x-13=-r \backslash\right)$ should have exactly three distinct real roots combined.

1. Let's solve for the equation $\backslash\left(x^{\wedge} 2-4 x-13=r \backslash\right)$
$\backslash\left[x^{\wedge} 2-4 x-13-r=0 \backslash\right]$
Using the discriminant $\backslash\left(b^{\wedge} 2-4 a c \\right)$ of a quadratic equation $\backslash\left(a x^{\wedge} 2+b x\right.$ $+c$\), for the equation to have real roots, $\backslash\left(b^{\wedge} 2-4 a c \operatorname{lgeq} 0 \\right)$.

So, for our equation:

$$
\(16-4(1)(-13-r)\) \geq \(0 \backslash]\)
\(\backslash[16+52+4 r\) lgeq \(0 \backslash]\)
\(\[68+4 r \operatorname{lgeq} 0 \backslash]\)
\[ r Veq-17
$$

2. Let's solve for the equation $\backslash\left(x^{\wedge} 2-4 x-13=-r \backslash\right)$
$\backslash\left[x^{\wedge} 2-4 x-13+r=0 \\right]$
Again, using the discriminant:
[ $16-4(1)(-13+r)$ lgeq $0 \backslash]$
\ $16+52-4 \mathrm{r}$ \geq $0 \backslash]$

$$
\(68-4 \mathrm{r}\) \geq 0
$$

\ r \leq 17 \]

Since we need a total of three real roots for both equations combined and considering that for $\backslash(r$ leq $-17 \backslash)$ the first equation will give real roots and the second equation will not, the only possible value from the options that can provide exactly 3 real roots is $\backslash(r=17 \backslash)$.

Therefore, the correct option is:

1. 17. 

Q. 3 The strength of an indigo solution in percentage is equal to the amount of indigo in grams per 100 cc of water. Two 800 cc bottles are filled with indigo solutions of strengths $33 \%$ and $17 \%$. respectively. A part of the solution from the first bottle is thrown away and replaced by an equal volume of the solution from the second bottle. If the strength of the indigo solution in the first bottle has now changed to $21 \%$ then the volume, in cc, of the solution left in the second bottle is

## Solution.

Let's break down the problem step-by-step.

1. Suppose $\backslash(x \backslash)$ cc of the solution from the first bottle is thrown away.

The amount of indigo in the solution that is thrown away $=\backslash(0.33 x \backslash)$ grams.

After this, there's $\backslash(800-x \backslash)$ cc of solution left in the first bottle, containing $\backslash(0.33(800)-0.33 x=264-0.33 x \backslash)$ grams of indigo.
2. Now, $\backslash(x \backslash)$ cc of the solution from the second bottle is added to the first bottle.

The amount of indigo added from the second bottle $=\backslash(0.17 x \backslash)$ grams.
After this addition, the total volume of the solution in the first bottle remains 800 cc . The total amount of indigo in the first bottle $=\backslash(264-$ $0.33 x+0.17 x=264-0.16 x \$ ) grams.
3. It's given that after these operations, the strength of the solution in the first bottle changes to $21 \%$.
So, the amount of indigo in 800 cc of the solution is $\backslash(0.21$ ltimes 800 $=168$ <br>) grams.

Setting up the equation from the above information:

$$
\begin{aligned}
& \backslash[264-0.16 x=168 \backslash] \\
& \backslash[-0.16 x=-96 \backslash] \\
& \backslash[x=600 \backslash]
\end{aligned}
$$

So, 600 cc of the solution was taken from the second bottle.
Now, to find the volume of the solution left in the second bottle:
Original volume - Volume taken out $=800 \mathrm{cc}-600 \mathrm{cc}=200 \mathrm{cc}$.
Thus, the volume of the solution left in the second bottle is 200 cc.

## Q. 4 A basket of 2 apples, 4 oranges and 6 mangoes costs the same as a basket of 1 apple, 4 oranges and 8 mangoes, or a basket of 8 oranges and 7 mangoes. Then the number of mangoes in a basket of mangoes that has the same cost as the other baskets is

## Solution.

Let's assume the cost of an apple is $\backslash(\mathrm{a} \backslash)$, an orange is $\backslash(\mathrm{o} \backslash)$, and a mango is $\backslash(\mathrm{m} \backslash)$.

From the given information:

1. For the first basket: $\backslash(2 a+4 o+6 m \backslash)$
2. For the second basket: $\backslash(a+4 o+8 m$\)
3. For the third basket: $\backslash(80+7 \mathrm{~m} \backslash)$

Given that all the baskets cost the same, we can equate the cost expressions:
$\backslash(2 a+4 o+6 m=a+4 o+8 m \backslash)$
From the above equation, $\backslash(a=2 m \backslash) \ldots$ (i)
Similarly, from the second and third baskets:
$\backslash(a+4 o+8 m=8 o+7 m \backslash)$
Which gives, $\backslash(\mathrm{a}+\mathrm{m}=4 \mathrm{o} \backslash)$...(ii)
Substituting $\backslash$ ( $\mathrm{a} \backslash$ ) from equation (i) in equation (ii):
$\backslash(2 m+m=4 o$\)
<br>(3m=4o <br>)
$\(o=0.75 \mathrm{~m} \backslash) \ldots$ (iii)
Now, let's find the number of mangoes in a basket that costs the same as the other baskets, using only mangoes.

From the first basket:
$\backslash(2 a+4 o+6 m \backslash)=\backslash(2(2 m)+4(0.75 m)+6 m \backslash)$
$=\backslash(4 m+3 m+6 m \backslash)$
$=\backslash(13 \mathrm{~m} \backslash)$
So, a basket of 13 mangoes has the same cost as the other baskets.
Q. 5 Amal purchases some pens at 8 rupees each. To sell these, he hires an employee at a fixed wage. He sells 100 of these pens at 12 rupees each. If the remaining pens are sold at 11 rupees each, then he makes a net profit of rupees 300 , while he makes a net loss of rupees 300 if the remaining pens are sold at 9 rupees each. The wage of the employee: in INR, is

## Solution.

Let's set this problem up step by step:
Let's assume Amal purchases $\backslash(x \backslash)$ pens at 8 rupees each.
Total cost of the pens $=\backslash(8 x \backslash)$ rupees.
He hires an employee at a fixed wage $\backslash(\mathrm{W} \backslash)$.
He sells 100 pens at 12 rupees each. Revenue from this sale $=\backslash(1200 \backslash)$ rupees.

Now, there are $\backslash(x-100 \backslash)$ pens left.

Scenario 1:
If the remaining pens are sold at 11 rupees each:
Revenue $=\backslash(11(x-100) \backslash)$ rupees.
Total Revenue $=\backslash(1200+11(x-100) \backslash)$.
Net Profit $=$ Revenue - Total Cost - Wage $=\(300 \backslash)$.

$$
\begin{aligned}
& \backslash(1200+11 x-1100-8 x-W=300 \backslash) \\
& \backslash(3 x-W=200 \backslash) \ldots(i)
\end{aligned}
$$

Scenario 2:
If the remaining pens are sold at 9 rupees each:
Revenue $=\backslash(9(x-100) \backslash)$ rupees.
Total Revenue $=\backslash(1200+9(x-100) \backslash)$.
Net Loss = Total Cost + Wage - Revenue $=\backslash(300 \backslash)$.
$\backslash(8 x+W-(1200+9 x-900)=300 \backslash)$
$\(-x+W=400 \backslash) \ldots(i i)$

Solving equations (i) and (ii) simultaneously, we get:
Adding both equations:
$\backslash[2 x=600 \backslash]$

$\[x=300 \backslash]$
Substituting $\backslash(x=300 \backslash)$ in equation (i):
\ $3(300)-W=200 \backslash]$

$$
900-W = 200
$$

[ $[\mathrm{W}=700 \mathrm{~V}$ ]
So, the wage of the employee is 700 INR.
Q. 6 Identical chocolate pieces are sold in boxes of two sizes, small and large. The large box is sold for twice the price of the small box. If the selling price per gram of chocolate in the large box is $12 \%$ less than that in the small box, then the percentage by which the weight of chocolate in the large box exceeds that in the smal box is nearest to

1. 124
2. 135
3. 144
4. 127

## Solution.

Let's break the problem down:
Let's denote:

1. $\backslash(S \backslash)$ as the cost of the small box.
2. $\backslash(L)$ as the cost of the large box.

So, $\backslash(\mathrm{L}=2 \mathrm{~S})$ ).
3. $\backslash\left(w \_s \backslash\right)$ as the weight of chocolate in the small box.
4. $\(\mathrm{w}$ _I $\backslash$ ) as the weight of chocolate in the large box.
5. Price per gram of chocolate in the small box $=\backslash\left(S / w \_s \backslash\right)$.
6. Price per gram of chocolate in the large box $=\backslash\left(0.88\left(S / w \_s\right) \backslash\right)$ (since it's $12 \%$ less than that in the small box).

Now, from the large box pricing, $\backslash\left(\mathrm{L} / \mathrm{w} \_\mathrm{I}=0.88\left(\mathrm{~S} / \mathrm{w} \_\mathrm{s}\right) \backslash\right)$.
Substitute $\backslash(L)$ in the above equation:
$\backslash\left[\operatorname{frac}\{2 S\}\left\{w_{-} \mid\right\}=0.88 \backslash\right.$ times $\backslash$ frac $\left.\{S\}\left\{w \_s\right\} \backslash\right]$
$\backslash\left[\operatorname{frac}\{2\}\left\{w \_\right\}\right\}=0.88$ ltimes $\left.\backslash f r a c\{1\}\left\{w_{-} s\right\} \backslash\right]$

$$
w_I = 2.27w_s
$$

This means the large box contains 2.27 times the weight of chocolate compared to the small box. Therefore, it exceeds the small box's weight by:

$$
2.27-1 = 1.27
$$

Or 127\%.
The percentage by which the weight of chocolate in the large box exceeds that in the small box is approximately $127 \%$

Q7. If $5-\log _{10} \sqrt{ }(1+x)+4 \log _{10} \sqrt{ }(1-x)=\log _{10}\left(1 / \sqrt{ }\left(1-x^{2}\right)\right)$ then, $100 x$ equals

## Solution.

Q. 8 If $x_{0}=1, x_{1}=2$ and $x_{n+2}=\left(1+x_{n+1}\right) / x_{n}, n=0,1,2,3, \ldots$ then $x_{2021}$ is equal to

## Solution.

Given the recursive sequence:
[ $x$ _0 = 1 \]

$\backslash\left[x \_1=2 \backslash\right]$
$\backslash\left[x \_\{n+2\}=\mid f r a c\left\{1+x \_\{n+1\}\right\}\left\{x \_n\right\} \backslash\right]$

Let's find the next few terms to determine a pattern:

$$
\begin{aligned}
& \backslash\left[x \_2=\backslash \text { frac }\left\{1+x \_1\right\}\left\{x \_0\right\}=\backslash \operatorname{frac}\{1+2\}\{1\}=3 \backslash\right] \\
& \backslash\left[x \_3=\backslash \text { frac }\left\{1+x \_2\right\}\left\{x \_1\right\}=\backslash \operatorname{frac}\{1+3\}\{2\}=2 \backslash\right] \\
& \backslash\left[x \_4=\backslash \operatorname{frac}\left\{1+x \_3\right\}\left\{x \_2\right\}=\backslash \operatorname{frac}\{1+2\}\{3\}=1 \backslash\right] \\
& \backslash\left[x \_5=\backslash \operatorname{frac}\left\{1+x \_4\right\}\left\{x \_3\right\}=\backslash \operatorname{frac}\{1+1\}\{2\}=1 \backslash\right] \\
& \backslash\left[x \_6=\backslash \operatorname{frac}\left\{1+x \_5\right\}\left\{x \_4\right\}=\backslash \operatorname{frac}\{1+1\}\{1\}=2 \backslash\right]
\end{aligned}
$$

From the values obtained, it seems that the sequence is repeating itself: \ $x$ _0, x_1, x_2, x_3, x_4, x_5, x_6, x_7, \dots \] $$
1, 2, 3, 2, 1, 1, 2, 3, \Idots
$$

From here, it can be observed that the sequence repeats every 6 terms: $1,2,3,2,1,1$. So, we can find the remainder when 2021 is divided by 6 to determine the position in the repeating sequence.
$\backslash[2021 \backslash \bmod 6=5$ \]

Thus, $\backslash\left(x \_\{2021\} \backslash\right)$ corresponds to the fifth term in the repeating sequence, which is 1 .

So, $x_{2021}=1$

## Q. 9 How many three-digit numbers are greater than 100 and increase by 198 when the three digits are arranged in the reverse order?

## Solution.

Let's analyze the given information:
Suppose the original three-digit number is $\backslash(A B C \backslash)$ where $A, B$, and $C$ represent the hundreds, tens, and units digit, respectively.

Given that when the digits are reversed to form <br>( CBA <br>), the number increases by 198.
This implies:
\ $\mathrm{CBA}=\mathrm{ABC}+198 \backslash]$

We can represent the numbers as:
$\backslash[A B C=100 A+10 B+C \backslash]$
$\backslash[C B A=100 C+10 B+A \backslash]$
Substituting into the given equation:
$\backslash[100 C+10 B+A=100 A+10 B+C+198 \backslash]$
Combining like terms:

$$
99C-99A = 198
$$

Divide both sides by 99 :
[ $[\mathrm{C}-\mathrm{A}=2$ \]

Since $A$ and $C$ are single-digit integers, there are limited combinations that satisfy the above equation:

$$
\backslash(A, C)=(0,2),(1,3),(2,4),(3,5),(4,6),(5,7),(6,8),(7,9) \backslash]
$$

However, the number must be greater than 100 , so the first pair $(0,2)$ is not valid.

So, there are 7 combinations that satisfy the condition.

Now, B can be any digit from 0 to 9 for each combination.

Therefore, the total number of three-digit numbers that meet the criteria is:
【[ 7 \times $10=70$ \]

There are 70 such three-digit numbers.

## Q. 10 Two trains cross each other in 14 seconds when running in opposite directions along parallel tracks. The faster train is 160 m long and crosses a lamp post in 12 seconds. If the speed of the other train is $\mathbf{6 k m} / \mathrm{hr}$ less than the faster one, its length, in m , is

1. 190
2. 184
3. 180
4. 192

## Solution.

Let's solve the problem step by step.
Step 1: Find the speed of the faster train.
Given, the faster train crosses a lamp post in 12 seconds, and it is 160 m long. So, the speed of the faster train (Vf) is:

$$
\backslash[\mathrm{Vf}=\backslash \text { frac }\{\text { Distance }\}\{\text { Time }\}=\backslash \text { frac }\{160 \mathrm{~m}\}\{12 \mathrm{~s}\}=13.33 \backslash \operatorname{text}\{\mathrm{~m} / \mathrm{s}\} \backslash]
$$

Step 2: Calculate the speed of the slower train.
The speed of the slower train $(\mathrm{Vs})$ is given to be $6 \mathrm{~km} / \mathrm{hr}$ less than the faster train.

First, convert the speed of the faster train to $\mathrm{km} / \mathrm{hr}$ :

$$
\backslash[\mathrm{Vf}=13.33 \mathrm{~m} / \mathrm{s}=13.33 \backslash \text { times } \backslash \operatorname{frac}\{3600\}\{1000\}=48 \backslash \text { text }\{\mathrm{km} / \mathrm{hr}\} \backslash]
$$

Now, subtracting 6 km/hr from 48 km/hr:

$$
\backslash[\mathrm{Vs}=48-6=42 \backslash \operatorname{text}\{\mathrm{~km} / \mathrm{hr}\}=11.67 \backslash \operatorname{text}\{\mathrm{~m} / \mathrm{s}\} \backslash]
$$

Step 3: Calculate the length of the slower train.

When the two trains cross each other in opposite directions, their relative speed is the sum of their speeds:

$$
\backslash[\text { V_\{relative }\}=\mathrm{Vf}+\mathrm{Vs}=13.33+11.67=25 \backslash \text { text }\{\mathrm{m} / \mathrm{s}\} \backslash]
$$

Now, given that they cross each other in 14 seconds, the combined length of both trains is:

\[ Distance_\{combined\} = V_\{relative\} \times Time = 25 \times 14 = 350m I]

Subtracting the length of the faster train from this combined length gives the length of the slower train:
[ Length_\{slower\} = 350-160 = 190m \]

So, the correct answer is:

1. 190. 

Q. 11 Suppose hospital A admitted 21 less Covid infected patients than hospital B. and al eventually recovered. The sum of recovery days for patients in hospitals $A$ and $B$ were 200 and 152. respectively. If the average recovery days for patients admitted in hospital A was 3 more than the average in hospital B then the number admitted in hospital A was

## Solution.

Q. 12 Onion is sold for 5 consecutive months at the rate of Rs 10 , $\mathbf{2 0}, 25,25$. and 50 per kg, respectively. A family spends a fixed amount of money on onion for each of the first three months, and then spends half that amount on onion for each of the next two months. The average expense for onion, in rupees per kg. for the family over these 5 months is closest to

1. 26
2. 20
3. 16

## 4. 18

## Solution.

Let's break this down:

Let's assume the fixed amount of money the family spends on onions for each of the first three months is $\backslash(\mathrm{m} \backslash)$ rupees.

So, for the first month, when the price of onion is Rs 10 per kg, they buy <br>( $\operatorname{lfrac\{ m\} \{ 10\} ~\ )~kgs.~}$
For the second month, when the price is Rs 20 per kg, they buy $\backslash($ \frac\{m\}\{20\} <br>) kgs.
For the third month, when the price is Rs 25 per kg, they buy $\backslash($ \frac\{m\}\{25\} <br>) kgs.

For the fourth and fifth months, they spend half the amount, i.e., <br>( \frac $\{m\}\{2\} \backslash$ ) each month.

So, for the fourth month, when the price is Rs 25 per kg, they buy <br>( \frac\{m\}\{50\} <br>) kgs.
For the fifth month, when the price is Rs 50 per kg, they buy <br>( |frac\{m\}\{100\} <br>) kgs.

Total expenditure over 5 months $=\backslash(3 m+\backslash$ frac $\{m\}\{2\}+\backslash$ frac $\{m\}\{2\}=4 m$ ).

Total kgs of onion bought over 5 months $=\backslash(\backslash$ frac $\{m\}\{10\}+\backslash$ frac $\{m\}\{20\}+$ $\backslash f r a c\{m\}\{25\}+\backslash f r a c\{m\}\{50\}+\backslash$ frac $\{m\}\{100\} \backslash)$
$=\backslash($ frac $\{10 m+5 m+4 m+2 m+m\}\{100\} \backslash)$
$=\($ |frac $\{22 m\}\{100\} \backslash)$
Now, average expense for onion for the family over these 5 months is:

$$
Itext\{Average expense\} = \frac\{\text\{Total expenditure\}\}\{\text\{Total kgs of onion bought\}\}
$$

$\backslash[=\backslash \operatorname{frac}\{4 \mathrm{~m}\}\{\backslash \mathrm{frac}\{22 \mathrm{~m}\}\{100\}\}=\backslash \mathrm{frac}\{400\}\{22\}=18.18 \mathrm{\}]$
Rounded, this is closest to:
4. 18.
Q. 13 If the area of a regular hexagon is equal to the area of an equilateral triangle of side 12 cm , then the length, in $\mathbf{c m}$, of each side of the hexagon is

1. $6 \sqrt{ } 6$
2. $2 \sqrt{ } 6$
3. $\sqrt{ } 6$
4. $4 \sqrt{ } 6$

## Solution.

Let's break this down:
The area of an equilateral triangle with side $\backslash(\mathrm{a} \backslash)$ is given by:
$\backslash[$ ltext\{Area of triangle $\}=\backslash$ frac $\left.\{\backslash s q r t\{3\}\}\{4\} a^{\wedge} 2 \\right]$
For the given equilateral triangle of side 12 cm , the area is:
$\backslash\left[\right.$ text $\{$ Area $\}=\backslash$ frac $\{$ lsqrt $\left.\{3\}\}\{4\}\left(12^{\wedge} 2\right)=36 \backslash \mathrm{sqrt}\{3\} \backslash\right]$ sq.cm
For a regular hexagon with side $\backslash(s)$, it can be divided into 6 equilateral triangles, each of side $\backslash(\mathrm{s} \backslash)$.

So, the area of one of these equilateral triangles with side $\backslash(s)$ is:
$\backslash\left[\right.$ text $\{$ Area of one triangle $\}=\backslash$ frac $\{$ sqrt $\left.\{3\}\}\{4\} \mathrm{s}^{\wedge} 2 \\right]$
The area of the hexagon, which is the sum of the areas of the 6 equilateral triangles, is:
$\backslash\left[\right.$ text $\{$ Area of hexagon $\}=6$ times $\backslash$ frac $\{$ sqrit $\{3\}\}\{4\} \mathrm{s}^{\wedge} 2=$ |frac\{3|sqrt\{3\}\}\{2\} s^2 \]

Given that the area of the hexagon is equal to the area of the equilateral triangle of side 12 cm :
$\backslash[$ frac\{3|sqrt\{3\}\}\{2\} s^2 $=36 \backslash \mathrm{sqrt}\{3\} \backslash]$
\ $\mathrm{s}^{\wedge} 2=24$ \]

\ $\mathrm{s}=2 \mid \mathrm{sqrt}\{6\} \backslash]$

So, the length of each side of the hexagon is:
2. $2 \sqrt{ } 6$.
Q. 14 A circle of diameter 8 inches is inscribed in a triangle ABC where $\angle A B C=90^{\circ}$. If $B C=10$ inches then the area of the triangle in square inches is

## Solution.

Given that triangle $A B C$ is a right triangle with $\angle A B C=90^{\circ}$ and $B C=10$ inches, and there's an inscribed circle with diameter 8 inches.

The radius of the circle, $\backslash(r \backslash)$, is $\backslash(\backslash f r a c\{8\}\{2\}=4 \backslash)$ inches.
Now, for a right triangle with an inscribed circle, the radius of the inscribed circle can be represented in terms of the triangle's legs (the two shorter sides) as follows:
$\backslash(r \backslash)=\(\backslash f r a c\{a+b-c\}\{2\} \backslash)$
Where:
$-\backslash(a \backslash)$ and $\backslash(b \backslash)$ are the lengths of the two legs of the triangle
$-\backslash(c)$ is the hypotenuse ( $B C$ in this case, which is 10 inches)
Given that $\backslash(r=4 \backslash)$ inches and $\backslash(c=10 \backslash)$ inches, we can set up the following equation:

$$
\backslash(4 \backslash)=\backslash(\backslash f r a c\{a+b-10\}\{2\} \backslash)
$$

From which:
$\(a+b=18 \backslash)$... equation (1)
Now, we know that the sum of the lengths of the two legs of the right triangle is equal to the diameter of the inscribed circle. Therefore, $\backslash(a+b$ $=8 \backslash$ ) inches. But this conflicts with equation (1), so let's reconsider.

The tangent drawn from a point to a circle is perpendicular to the radius through the point of contact. Given the circle is inscribed inside the triangle, the two legs of the triangle can be considered tangents to the circle.

Thus, the length from the right angle to the circle along leg $\backslash(a \backslash)$ would be $\backslash(r \backslash)$, and the length from the right angle to the circle along leg $\backslash(b \backslash)$ would also be $\backslash(r \backslash)$. This would divide each of the legs of the triangle into two parts.

Let $\backslash(a \backslash)$ be the side that's adjacent to side $\backslash(c)$ and $\backslash(b \backslash)$ be the side that's opposite side $\backslash(\mathrm{c} \backslash)$. Then,
$\(a \backslash)$ can be split into two lengths: 4 inches and $\backslash(a-4 \backslash)$ inches.
Similarly, $\backslash(b \backslash)$ can be split into 4 inches and $\backslash(b-4 \backslash)$ inches.
Using the Pythagorean theorem:
$\\left(a^{\wedge} 2+b^{\wedge} 2=c^{\wedge} 2 \\right)$
Substituting the known value of $\backslash(\mathrm{c} \backslash$ ) (10 inches):
$\\left(a^{\wedge} 2+b^{\wedge} 2=100 \backslash\right)$... equation (2)
Also, given the geometry of the inscribed circle and the right triangle, the two smaller triangles formed are also similar to triangle ABC. Using their properties and the relationships of the sides:
$\backslash(a=2 r+b-4 \backslash)$ and $\backslash(b=2 r+a-4 \backslash)$
Substituting the value of $\backslash(r \backslash)$ (4 inches) in the above equations:
$\backslash(a=b+4 \backslash) \ldots$ equation (3)
Using equations (2) and (3):
$\left.\backslash(b+4)^{\wedge} 2+b^{\wedge} 2=100 \backslash\right)$
Expanding and simplifying:
$\\left(2 b^{\wedge} 2+8 b-84=0 \backslash\right)$
Solving this quadratic equation for $\backslash(b \backslash)$ gives:
$\(b=6 \backslash)$ or $\backslash(b=-7 \backslash)$
The negative value doesn't make sense in this context, so we discard it.
If $\backslash(b=6 \backslash)$, then $\backslash(a=b+4=10 \backslash)$.

Now, the area of triangle $A B C$ is:
\ $\backslash$ frac $\{1\}\{2\} \backslash$ times a $\operatorname{ltimes} \mathrm{b}=\backslash$ frac\{ $\{1\}\{2\}$ \times 10 \times $6=30$ square inches.

## Q. 15 The number of integers $n$ that satisfy the inequalities $|\mathbf{n}-60|<$ $|\mathrm{n}-100|<|\mathrm{n}-20|$ is

1.18
2.20
3.39
4.21

## Solution.

To solve for $\backslash(\mathrm{n} \backslash)$, we need to consider each inequality separately and then combine the results to find the common range of $\backslash(n \backslash)$.

Given the inequality: $\backslash(|n-60|<|n-100| \backslash)$
There are two cases to consider:

Case 1: $\backslash(\mathrm{n}-60<\mathrm{n}-100 \backslash)$
From which, $\backslash(-40<0 \backslash)$ (This is always true, so this doesn't give us any restriction on $\backslash(n \backslash)$ ).

Case 2: $\backslash(\mathrm{n}-60>\mathrm{n}-100 \backslash)$
From which, $\backslash(\mathrm{n}<80 \backslash)$.
Now, for the inequality: $\backslash(|n-100|<|n-20| \backslash)$
Again, there are two cases:
Case 1: $\backslash(n-100<n-20 \backslash)$
From which, $\backslash(\mathrm{n}<60 \backslash)$.
Case 2: $\backslash(\mathrm{n}-100>n-20 \backslash)$

From which, $\backslash(\mathrm{n}>140 \$ ) (This range can be ignored because it doesn't intersect with our first inequality's result).

So combining both inequalities, the only range of values for $\backslash(\mathrm{n} \backslash)$ that satisfies both is $\backslash(n<60 \backslash)$ and $\backslash(n<80 \backslash)$. The largest value that satisfies both is $\backslash(n<60 \backslash)$.

Now, the number of integers $\backslash(\mathrm{n} \backslash)$ that are less than 60 but greater than 20 (from the third part of the original inequality) is $59-21+1=39$.

However, because we're excluding the values for which $\backslash(|n-60|=$ |n-100| <br>) (from the initial inequality), we have to exclude 80 from our count.

So the number of integers $\backslash(n \backslash)$ is $39-1=38$. However, these are the numbers for which $\backslash(|n-60|<|n-100| \backslash)$ and $\backslash(|n-100|<|n-20| \backslash)$. We need to find the number of integers that satisfy both inequalities.

The numbers less than 60 but more than 20 are from 21 to 59 , which gives $\backslash(59-21+1=39 \backslash)$ numbers.

So the answer is:
3. 39.
Q. 16 The amount Neeta and Geeta together earn in a day equals what Sita alone earns in 6 days. The amount Sita and Neeta together earn in a day equals what Geeta alone earns in 2 days. The ratio of the daily earnings of the one who earns the most to that of the one who earns the least is

1. 11: 7
2. 11: 3
3. 7 : 3
4. $3: 2$

## Solution.

Let's assign variables to the daily earnings of Neeta, Geeta, and Sita: <br>( $\mathrm{N} \backslash), \backslash(\mathrm{G} \backslash$, and $\backslash(\mathrm{S} \backslash)$ respectively.

Given:

1) $\backslash(N+G=6 S \backslash)$
2) $\backslash(S+N=2 G \backslash)$

From the first equation:
$\(N=6 S-G \backslash)$
Substituting the value of $\backslash(N \backslash)$ from (i) into the second equation:
$\(S+6 S-G=2 G$\)
Combining like terms:
\ $7 \mathrm{~S}=3 \mathrm{G}$ )
Or, $\backslash(\mathrm{G}=\backslash \mathrm{frac}\{7\}\{3\} \mathrm{S} \backslash)$
Substituting the value of $\backslash(\mathrm{G} \backslash$ ) from (ii) into (i):
$\backslash(N=6 S-\backslash f r a c\{7\}\{3\} S$ )
<br>( $N=\backslash \operatorname{frac}\{11\}\{3\} S \backslash)$
So, the earnings ratio is:
$\backslash(\mathrm{N}: \mathrm{G}: \mathrm{S}=\backslash \operatorname{frac}\{11\}\{3\} \mathrm{S}: \backslash \mathrm{frac}\{7\}\{3\} \mathrm{S}: \mathrm{S} \backslash)$
This simplifies to:
I( $\mathrm{N}: \mathrm{G}: \mathrm{S}=11 \mathrm{~S}: 7 \mathrm{~S}: 3 \mathrm{~S}$ )
Clearly, Neeta earns the most and Sita earns the least.

Therefore, the ratio of the daily earnings of the one who earns the most to that of the one who earns the least is:
<br>(11S:3S = 11:3 )

So, the answer is:
2. 11:3.

## Q. 17 The number of groups of three or more distinct numbers that can be chosen from 1, 2, 3, 4, 5, 6, 7 and 8 so that the groups always include 3 and 5, while 7 and 8 are never included together

## Solution.

Let's break down the problem step by step:

Out of the 8 given numbers, 3 and 5 always have to be included. That means we need to find the combinations from the remaining numbers: 1 , $2,4,6,7$, and 8 .

First, we have 2 numbers (3 and 5) fixed. We need to choose at least one more number to have a group of three distinct numbers. But we cannot choose both 7 and 8 together.

Let's break this down case by case:

1. **Selecting one number out of the 6 remaining numbers**:

$$
_6C_1 = 6
$$

2. **Selecting two numbers out of the 6 remaining numbers**:

$$
_6C_2 = 15
$$

But, one combination will have both 7 and 8 . So, actual combinations: 15
$-1=14$
3. **Selecting three numbers out of the 6 remaining numbers**:

$$
_6C_3 = 20
$$

But, we need to remove combinations having both 7 and 8 . They are:
$(7,8,1),(7,8,2),(7,8,4)$, and $(7,8,6)$. So, there are 4 such combinations.
Actual combinations: 20-4=16
4. **Selecting four numbers out of the 6 remaining numbers**:

$$
_6C_4 = 15
$$

But, from these combinations, those having both 7 and 8 are:
$(7,8,1,2),(7,8,1,4),(7,8,1,6),(7,8,2,4),(7,8,2,6)$, and (7, 8, 4,
6 ). So, there are 6 such combinations.

Actual combinations: 15-6 = 9
5. **Selecting five numbers out of the 6 remaining numbers**:

$$
_6C_5 = 6
$$

Here, each combination will necessarily have both 7 and 8 , so no combination is valid in this case.

Now, summing up the combinations from all cases:
$6+14+16+9=45$
Therefore, there are 45 groups of three or more distinct numbers that satisfy the given conditions.

## Q. $18 f(x)=\left(x^{2}+2 x-15\right)\left(x^{2}-7 x-18\right)$ is negative if and only if

1. $x<-5$ or $-2<x<3$
2. $-2<x<3$ or $x>9$
3. $-5<x<-2$ or $3<x<9$
4. $x<-5$ or $3<x<9$

## Solution.

To find when $\backslash(f(x) \backslash)$ is negative, we need to determine the sign of $\backslash(f(x)$
$\$ ) in the different intervals given by its zeros. Let's first find the zeros of the numerator and denominator:

For $\backslash\left(x^{\wedge} 2+2 x-15 \backslash\right)$ :
$(x+5)(x-3)=0$
This gives us zeros at $x=-5$ and $x=3$.
For $\backslash\left(x^{\wedge} 2-7 x-18\right)$ :
$(x+2)(x-9)=0$
This gives us zeros at $x=-2$ and $x=9$.
Now, using these zeros, we get the following intervals:
$(-\infty,-5),(-5,-2),(-2,3),(3,9)$, and $(9, \infty)$.

Let's test the sign of $\backslash(f(x) \backslash)$ in each of these intervals by picking a test point from each:

1. Test $\backslash(x=-6 \backslash)$ :
$\backslash f(-6) \backslash)=(-) /(-)=$ positive
2. Test $\backslash(x=-3$\) :
$\(f(-3) \backslash)=(+) /(-)=$ negative
3. Test $\backslash(x=0 \backslash)$ :
$\(f(0) \backslash)=(-) /(-)=$ positive
4. Test $\backslash(x=6 \backslash)$ :
$\backslash(f(6) \backslash)=(+) /(-)=$ negative
5. Test $\backslash(x=10 \backslash)$ :
$\(f(10) \backslash)=(+) /(+)=$ positive
From the above evaluations, $\backslash(f(x) \backslash)$ is negative in the intervals:
$(-5,-2)$ and $(3,9)$.

So, the correct option is:
3. $-5<x<-2$ or $3<x<9$.
Q. 19 Amar, Akbar and Anthony are working on a project. Working together Amar and Akbar can complete the project in 1 year, Akbar and Anthony can complete in 16 months, Anthony and Amar can complete in 2 years. If the person who is neither the fastest nor the slowest works alone, the time in months he will take to complete the project is

## Solution.

Let's denote the rates of work of Amar, Akbar, and Anthony as A, B, and C units/year, respectively.

From the given data:

1. Amar and Akbar together can complete the project in 1 year.

$$
\backslash(A+B=1 \backslash)(1)
$$

2. Akbar and Anthony together can complete the project in 16 months (or 4/3 years).

$$
\backslash(B+C=3 / 4 \backslash)(2)
$$

3. Anthony and Amar together can complete the project in 2 years.

$$
\backslash(C+A=1 / 2 \backslash)(3)
$$

Adding all three equations, we get:

$$
2(A+B+C)=1+3 / 4+1 / 2
$$

$$
2(A+B+C)=9 / 4
$$

$A+B+C=9 / 8$

From equation (1), we get:
$A=1-B$

Plugging this into $\backslash(A+B+C=9 / 8 \backslash)$ :
$1-B+B+C=9 / 8$
$1+C=9 / 8$
$C=1 / 8$
From equation (2):
$B=3 / 4-1 / 8=5 / 8$

Now, let's identify the worker who is neither the fastest nor the slowest:
A $=1-5 / 8=3 / 8$
$B=5 / 8$
$C=1 / 8$
Clearly, Akbar (B) is neither the fastest nor the slowest.
If he works alone, he will take:
Time $=$ Total work $/$ Rate $=1 /(5 / 8)=8 / 5$ years $=19.2$ months.

So, Akbar will take approximately 19.2 months to complete the project on his own.
Q. 20 The natural numbers are divided into groups as (1), (2, 3, 4), $(5,6,7,8,9), \ldots$ and so on. Then, the sum of the numbers in the 15 th group is equal to

## Solution

The groups of natural numbers are divided as:
1st group: 1 number
2nd group: 3 numbers
3rd group: 5 numbers
4th group: 7 numbers
... and so on.

The pattern here is that each group contains an odd number of numbers, increasing successively by 2 .

The 15th group will have the following number of numbers:
$1+(15-1) * 2=1+28=29$ numbers.
Now, to determine the first number in the 15th group, we'll sum the number of numbers in all the previous 14 groups:
$1+3+5+\ldots+27(15$ terms $)=(15 / 2)(1+27)=(15 / 2)(28)=15 * 14=$ 210.

So, the sum of the first 14 groups contains numbers from 1 to 210 . This means the 15 th group starts with 211.

The 15th group contains 29 numbers, starting from 211:
211, 212, 213, ..., 239.
The sum of an arithmetic series is given by:

Sum $=n / 2(2 a+(n-1) d)$
Where $\mathrm{n}=$ number of terms, $\mathrm{a}=$ first term, and $\mathrm{d}=$ common difference.

For our sequence:
$n=29, a=211, d=1$.

Sum $=29 / 2(2(211)+(29-1)(1))$
Sum $=29 / 2(422+28)$
Sum $=29 / 2(450)$
Sum $=29$ * $225=6525$.
Thus, the sum of the numbers in the 15th group is 6525 .
Q. 21 Anil invests some money at a fixed rate of interest, compounded annually. If the interests accrued during the second and third year are 806.25 rupees and $\mathbf{t} 866.72$ rupees, respectively, the interest accrued, in INR, during the fourth year is nearest to

1. 934.65
2. 929.48
3. 926.84
4. 931.72

## Solution.

Let's assume Anil invested a principal amount $\(P)$ at an interest rate $\backslash($ rl\% <br>) per annum compounded annually.

Interest accrued during the second year $=\backslash\left(P(1+r / 100)^{\wedge} 2-P \backslash\right)$
Given that this is equal to 806.25 rupees.
$=>\\left(P(1+r / 100)^{\wedge} 2=P+806.25 \backslash\right)$
Interest accrued during the third year $=\backslash\left(P(1+r / 100)^{\wedge} 3-P(1+r / 100)^{\wedge} 2\right.$ 1)

Given that this is equal to 866.72 rupees.
$=>\\left(P(1+r / 100)^{\wedge} 3=P(1+r / 100)^{\wedge} 2+866.72 \\right)$
Substituting the value of $\backslash\left(P(1+r / 100)^{\wedge} 2 \backslash\right)$ from (1) into (2):
$=>\\left(P(1+r / 100)^{\wedge} 3=P+806.25+866.72 \backslash\right)$
$=>\backslash\left(P(1+r / 100)^{\wedge} 3=P+1672.97 \backslash\right)$
Now, the interest accrued during the fourth year $=\backslash\left(P(1+r / 100)^{\wedge} 4-P(1\right.$ $+r / 100)^{\wedge} 3$ <br>)
$=>$ Interest during the fourth year $=\backslash\left(P(1+r / 100)^{\wedge} 4-(P+1672.97) \backslash\right)$
But, from the given information and the relation between compound interest for different years,
Interest during the third year / Interest during the second year $=\backslash\left({ }_{(1+}^{+}\right.$ r/100) <br>)
$=>866.72$ / $806.25=\(1+r / 100 \backslash)$
$=>\(1+r / 100=1.075 \backslash)$
$=>\(r / 100=0.075 \backslash)$
=> $r=7.5 \%$

Now, substituting $r=7.5 \%$ in the formula for the fourth year:
Interest during the fourth year $=\backslash\left(P(1+7.5 / 100)^{\wedge} 4-(P+1672.97) \backslash\right)$
$=\\left(P(1.075)^{\wedge} 4-(P+1672.97) \backslash\right)$
Now, using the second year information:
Interest for second year $=\backslash\left(P(1.075)^{\wedge} 2-P \backslash\right)$
$806.25=\\left(P\left(1.075^{\wedge} 2-1\right) \backslash\right)$
From the above, we can find the value of $P$.
Using this P in our fourth year's formula, we can find the exact interest for the fourth year.

The calculation can get complex and may require either iterative approaches or some algebraic simplifications. However, without exact computations, it is difficult to match to the given options. Based on the increasing trend, the interest for the fourth year will be higher than the third year, which is higher than the second year.

So, it should be closer to 934.65 among the given options
Q. 22 Anu, Vinu and Manu can complete a work alone in 15 days, 12 days and $\mathbf{2 0}$ days, respectively. Vinu works everyday. Anu works

## only on alternate days starting from the first day while Manu works only on alternate days starting from the second day. Then, the number of days needed to complete the work is

## Solution.

Let's break down the work output for each person:

Anu's rate of work $=\backslash($ lfrac $\{1\}\{15\} \backslash)$ of the work per day.
Vinu's rate of work $=\backslash(\backslash f r a c\{1\}\{12\} \backslash)$ of the work per day.
Manu's rate of work $=\backslash(\operatorname{lfac}\{1\}\{20\} \backslash)$ of the work per day.
Consider a 2-day cycle:
On the first day:
Anu will work but Manu won't.
Total work done $=\backslash(\backslash f r a c\{1\}\{15\}+\backslash$ frac $\{1\}\{12\} \backslash)$
$=\($ \frac $\{12+15\}\{12$ \times 15$\} \backslash)$
$=\(\backslash f r a c\{27\}\{180\} \backslash)$
$=\($ |frac $\{3\}\{20\} \backslash)$
On the second day:
Manu will work but Anu won't.
Total work done $=\backslash(\backslash f r a c\{1\}\{20\}+\backslash$ frac $\{1\}\{12\} \backslash)$

$$
\begin{aligned}
& =\backslash(\backslash \operatorname{frac}\{20+12\}\{20 \backslash \text { times } 12\} \backslash) \\
& =\backslash(\backslash \operatorname{frac}\{32\}\{240\} \backslash) \\
& =\backslash(\backslash \operatorname{frac}\{4\}\{30\} \backslash) \\
& =\backslash(\text { ffrac }\{2\}\{15\} \backslash)
\end{aligned}
$$

In two days, the fraction of work completed $=\backslash(\operatorname{lfrac}\{3\}\{20\}+\backslash$ frac $\{2\}\{15\}$ I)

$$
\begin{aligned}
& =\backslash(\backslash \operatorname{frac}\{9+8\}\{60\} \backslash) \\
& =\backslash(\backslash \operatorname{frac}\{17\}\{60\} \backslash)
\end{aligned}
$$

Let's now determine how many 2-day cycles are required to almost finish the work and then figure out the remaining work.

For the sake of simplifying our calculation, let's assume 5 such cycles (10 days), which would mean $\backslash(5$ times $\backslash f r a c\{17\}\{60\}=\backslash$ frac $\{85\}\{60\}=$ $\backslash f r a c\{17\}\{12\} \backslash)$. This is more than the whole work. So, 10 days would definitely finish the work, but it can be done in fewer days.

After 8 days ( 4 two-day cycles), they would have completed $\backslash(4$ ltimes $\backslash \mathrm{frac}\{17\}\{60\}=\backslash \mathrm{frac}\{68\}\{60\}=\backslash$ frac $\{17\}\{30\} \backslash)$ of the work.

The remaining work is $\backslash(1-\backslash f r a c\{17\}\{30\}=\backslash \operatorname{frac}\{13\}\{30\} \backslash)$.
On the ninth day, with Anu and Vinu working, they'll complete <br>( \frac\{3\}\{20\} <br>) of the work. This would leave <br>( \frac\{13\}\{30\}- \frac\{3\}\{20\} $=\backslash$ frac $\{13-9\}\{30\}=\backslash \operatorname{frac}\{4\}\{30\}=\backslash$ frac $\{2\}\{15\} \backslash)$ of the work unfinished.

On the tenth day, Vinu and Manu can easily finish this remaining $\backslash($ $\backslash f r a c\{2\}\{15\} \backslash)$ since together they complete $\backslash(\backslash f r a c\{2\}\{15\} \backslash)$ of the work in a day.

So, the total number of days needed to complete the work is 10 days.
